Experiment 1
Creation of a Virtual Machine

Aim

To create a virtual machine named Ubuntu using VMware Workstation by allocating virtual hardware resources and configuring the required settings.

Algorithm

1. Open VMware Workstation on the host computer.
2. Select the option to create a new virtual machine.
3. Choose the Typical configuration option.
4. Select the Ubuntu ISO image as the installation media.
5. Choose Linux as the guest operating system and select the appropriate Ubuntu version.
6. Enter the virtual machine name as Ubuntu and select a location to store its files.
7. Configure the virtual hard disk size.
8. Allocate memory and processor resources to the virtual machine.
9. Configure the network adapter. Select NAT to allow network access through the host.
10. Review the settings and finish creating the virtual machine.
11. Verify that the Ubuntu virtual machine appears in the VMware Workstation Library.

Implementation

Input

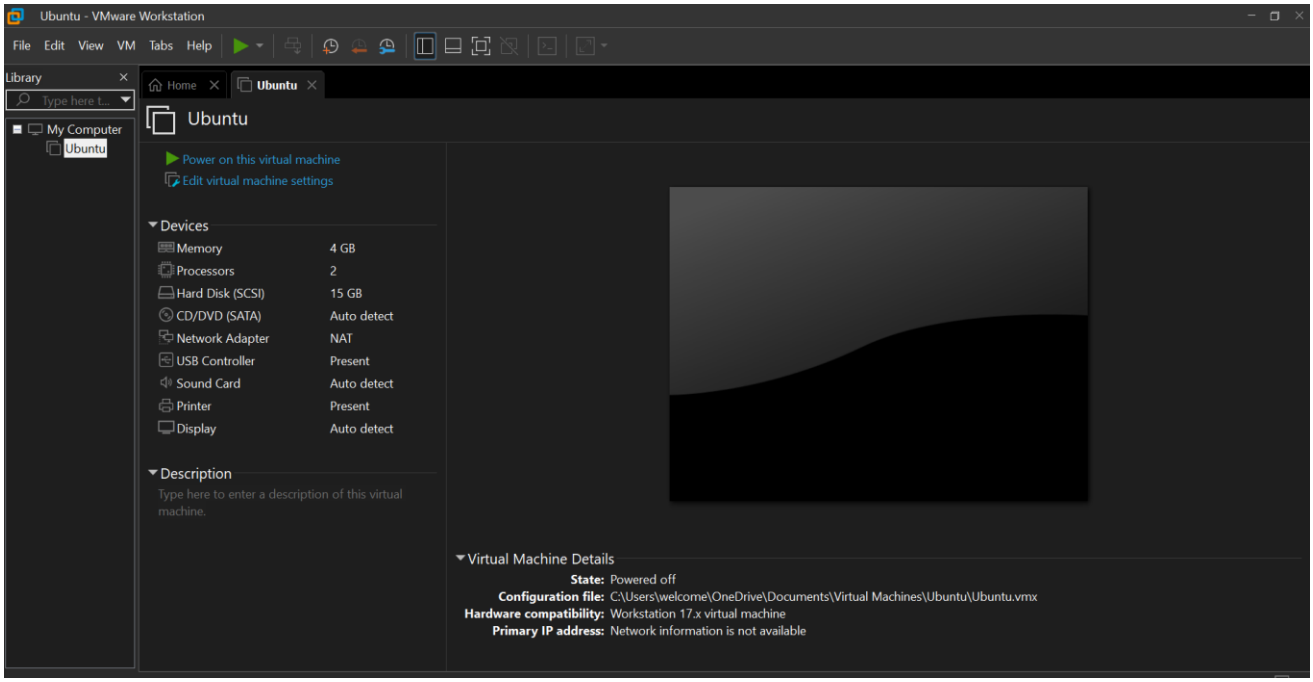

Figure 1: Ubuntu virtual machine configuration in VMware Workstation.

Output

The Ubuntu virtual machine is displayed in the VMware Workstation Library. The configuration shown in the supplied screenshot is:

Virtual machine name: Ubuntu

Memory: 4 GB

Processors: 2

Hard disk: 15 GB (SCSI)

CD/DVD: SATA – Auto detect

Network adapter: NAT

The virtual machine is shown as Powered off in the supplied screenshot. Powering it on and completing the Ubuntu installation are the next steps.

Result

Thus, an Ubuntu virtual machine was created successfully in VMware Workstation with the configured memory, processor, storage, and NAT network settings.
